

Microprocessor Controlled Greenhouse

Answer:

INPUT: Change in the value of Temperature, Light and Moisture is sensed by the sensors.

PROCESSING: After the values are changed to digital using ADC. Microprocessor will compare the values sensed by sensors with the preset/normal values stored.

e.g IF temperature is more than normal/preset then turn ON Fans Else OFF

IF light is more than normal/preset value then turn OFF lamps Else ON

IF moisture is more than normal/preset value then turn OFF water sprinkler
Else ON

OUTPUT: Fans turn ON or OFF to maintain required temperature

Lamps turn ON or OFF to control level of light in the greenhouse

Water sprinklers turn ON or OFF to maintain moisture level
